In this lecture, I am going to tell you how to make a contract in a 3D Chakra, how many units are required, how many bags are required, how many units of electricity are required, how much is required in a 3D Chakra and how much is required in a Glass Chakra. Then, how to use that inventory automatically will be managed. If the inventory is 100 bags, then it will be used.

Now, I will see what all things have to be added and what not to be added. Plus, everything that is being gated out. All gate passes have to be made in this contract.

Now, I will explain the name, date, which variant is it, how much is it, ok. And, you have saved it. So, it has its own format.

So, it is saved in the cloud. And, when the gate pass is given to a client, then in its ledger, we have fixed a date at the backend. That, brother, allow me, I want 13 MM.

So, I am giving the backend of 13. It will be 6. And, we can change that. So, that ledger automatically increases.

Ok. On the finance side, when the payment will be received, as soon as the payment is received, the ledger will be managed. Ok.

When the drop-down menu is opened, the client can select it. If we want to manually put the client on the board, then we have to manually feed it. And, the client gives the variant from there.

And, we will give that variant on which link. So, we can easily change it. So, according to that, the ledger will automatically be saved.

Ok. So, this is on the finance side. Now, on the finance side.

So, our ledger, which we are doing manually, I want it to be automatically fixed. And, everything is saved in the data. Everything is being saved in the cloud.

Ok. Now, everything, even the vouchers that we are making for the factory, I will make that automatic too. Then, the daily payments that are being issued, we can make the vouchers online.

Till now, we are doing it on the finance side. The paper vouchers that are signed at home, we don't want to keep that. Complete data stored on the cloud.

Complete. For years. It is completely manual.

It is manual. So, I want to shift it completely. I want to do a complete paper test.

If there is any payment, if there is my approval, then sir, like, I will give it to the grain seller. Or, I

will give it to the material seller, the chiller seller. Make the vouchers.

Which is the factory's, which is the head office's payment. All the expenses. Each day, if you feed, all the payments will be received this month.

But, if you do not. Because, at the same time, they have saved money in a separate account. One is expense out.

I am talking about the other thing that, this month, there is a cash wise expense out in front of us. If there is 50, so, 50 or 50, we will get to know every month, we store it. Can I add one more thing to this? What? That our company does a Daily Basis Price Call, i.e., we call it as Cost Price.

Now, the cost factor is that we have a major contributor, the price fluctuates, but it is increasing because of the current situation, otherwise it wouldn't be so much. But on a daily basis, let's say, we have so many units of electricity, if we add this, it will enter from there. How many units are there? So, how many units are there, how much production is there, so our daily basis average cost will increase.

We can do that, but then we have to find out the actual P&L. No, then we have to feed the formula. No, we have to feed the formula.

So, in that, you have written the starting units, which variants are being made. So, you have started the production. When people will end the production, then you will tell them that your starting unit will be coming in the beginning.

Suppose, which variants were started. So, if the ending unit is 1500, then 1000 units are consumed. So, we already have the data.

So, whatever we have to do there. No, but in the back end, we have written the unit electricity rate. Yes, we have to write that.

And we have written the price of dal. We know that in this shift, today, 50 bags of bilberts were consumed. 1000 units were also consumed.

So, the median was this much. And there were two people, who were the head operator and the assistant. In every shift, we have a head operator and an assistant.

There are two plants. So, in the drawback, plant 1 and plant 2 will also be used. So, plant 1 and plant 2 will also be used.

This is such a comprehensive. So, I am thinking that when we feed that, how much is the unit electricity. Because electricity fluctuates with the rate.

So, our main draw material is electricity. Which is 90%, almost 90% of our cost. Which is the

mean price of dal.

Nowadays, there are many things. Because they are made of petroleum. And nowadays, there is no electricity.

So, petroleum has a very good price. But usually, I don't do that much till 6 months. The same rates are there.

If you are doing the production end, then I have also done this. This is also a little interesting. You can see that.

But they have cut the feed. But everyone is coming. So, they will not be trained.

When it will be implemented. So, it will not be screened. It will not be screened.
