Why did it happen? Because no one has asked me before. No one has asked you before. Sorry.

I have shown you the purchase model. How it works. No, I have not shown it to you.

You have not shown it to me. So, what is the purchase model? Purchase is that we will go here. We will select the grain type.

A, B, C, D, whatever it is. After that we will see the numbers. We have taken 45.

We have taken the grain type. Like today, Today we have taken 50. According to me, it is 28,000.

So, the rate was 28,000. Now it has increased to 28,600. So, it is 8,000.

So, it becomes 40,30,000. That is 14,30,000. Ok.

Today's purchase rate. Spot is below you. It is in the market.

If you share it, it will enter. We can enter the source. There are 2-3 vendors.

So, if I go to vendors and enter a name. In the spot market, there are 2-3 vendors. So, if I enter the name of the vendor, it will enter.

So, this will also happen. So, we have actually entered in which condition it is right. We are using multiple.

And when you will add me, I will tell the rate of everyone. The one with whom we will sell more, it will be more comprehensive. So, it will be more transparent.

Ok. So, I saved it. It is done.

So, the rate is 28,600. It is 14,30,000 in the spot market. It is saved.

Yes, it is saved here. So, you have talked about the bags that are coming. Sometimes it is more than 10,000.

Sometimes it is more than 10,000. So, I have managed that thing. How? So, this was your purchase entry.

See, in our shop, every document is purchased. Today it is 50, tomorrow it is 100. This is just your purchase entry.

So, from the time it comes, it is done by hand. Now, the consumption of this will be here. For example, just now you put green in 50.

Ok. Yes. So, I have done this.

This is like your production is going on. I will show you some images. You said that you can put different types of greens in a variant.

There are three types of greens in one variant. Now, we will go to the variant. We will add it.

Now, we will say that different types of greens are being put in this. So, which green has to be increased by how much percent? So, here you can change the percentage. This is create variant.

Among us, there are three variants. The formula of all three is the same. So, we have to set it first.

So, whenever we do neo production, we will select variants. So, automatically the product will be like this. So, the formula will be like this.

And according to it, whatever is being used, consumed, whatever gram is being made, here you have gram. So, what is the variant? So, when we will buy grain type ABC, then we will put grain. So, according to that, we will take it from there.

Like you have put grain A. Now, in this, I have got a variant. In this, grain A is 80%. Now, the variant that is being made, A is grain ABC.

So, this is variant A. So, in variant A, A is 80%. O is 13%. O is 5%.

So, in variant A, A has got to know that I want these three things. So, our system has got to know what is the percentage. Now, when you are buying grain, those are just bags.

Now, the rate has increased a lot. Now, our system will check whether the entry of the bag is equal to the previous one or not. If it is not equal, then its entry rate has come.

Now, what will happen? First of all, with the money of the previous stock, your variant will start producing. Production will know what percentage is required and how many grams to produce. So, according to that, the bags that you have in the stock of grain, a bag of 25,000 grams, means, how many bags are there? 25,000.

When the variant is made, it is 6.5 grams. 6.5 grams divided by 80 percent will be this. 5.5 percent will be this and the remaining percent will be this.

So, according to that, 80 percent of the grains will be reduced from your inventory. I have to reduce it from this. I have to make a variant.

Obviously, a 6.5 gram variant is not enough. 100 meters, 70,000 meters, 100,000 meters are being made. So, its calculation is being done that I have to reduce 80 percent of the stock of

grains.

I have to reduce 5.5 grams and the remaining will be reduced. So, your raw material will be automatically reduced. Do you understand? The raw material will be automatically reduced and the finished goods will also be automatically reduced.

And then, because it is FIFO, the more goods are produced, the system knows that the old goods are finished and the new goods are automatically reduced. I am managing it in this way. I am managing it in this way.

You will go to the cost price. You will get to know that the variant of 1 in plant A is 70,000. This is the rate of each production.

Here, you have the rate of each production. This is the rate of each production. This is the rate of each production.

And the amount of goods consumed, the amount of units consumed, the amount of bags consumed, you get the rate of per meter. But, per meter, is it only 100 dollars? No, you know that. Because, in raw material, you said that there are bags also.

The price that is generated, the rate generated per meter, there is always In gross rate, direct cost is known. Direct cost is the unit of property which are these products. Unit of electricity, units of gas, labor, rent of the factory or transportation.

If we add this percentage, this will be direct cost. This plus 20-25% profit, this becomes the selling price. This is direct cost.

Now, when we calculate P&L, I will draw a page. Selling price minus these direct costs becomes the gross profit. Now, from this, you will get administrative salaries, office expenses, plus interest payments or taxes.

If there is a cost of fund, then you will have to take money from the bank. If you minus all these, it becomes net profit. So, we will always calculate the operating cost.

Just to make the calculation easier. Direct cost minus the selling price becomes the gross profit. From that, administrative, interest, taxes, minus cost becomes the net profit.

So, all this is gross profit. All this is gross profit. And this is depending on the price of your bags.

And calculating the current of electricity on that day, this is the opposite. The money of the bags has changed. You don't have to calculate the whole bag.

You will come here. You will see the production on that day. On this day's production, what is the expected price? At what meter angle? If a bag was of Rs.

25,000 and now it is of Rs. 1,00,000. So, the money has already increased automatically in production.

When you will come here. You don't have to do anything manually. You will see here.

You will say that this electricity unit has also increased the money. So, you don't have to calculate the whole bag. You will find out that in this production, the electricity bill of all the units consumed, the total electricity cost has also increased.

So, on any particular day, you can go to the bank and change the electricity cost. For example, I was saving in the last production. Now, I did it after 2 days.

But, after 2 days, the electricity bill was increasing. That is wrong. So, you can change it.

And then I will give you the admin access. So, you can do it. Or if you want to give the right to someone else, if you want to give the right to the production, then you can give it to him.

Or you can give it to him. You can edit the bag data. Otherwise, everyone has access.

Everyone has access. You have saved it. You have saved it.

It is nothing. If you have started the production, then whatever you have to do carefully, you have started it, then it will start. If I give the access to the editor directly, then anyone can do it later or later.

So, if you say that this right is in it, then you can give it. You can say that I have it. I want to go and do it.

Yes, you can go. In this, the cost you are editing now, only electricity and bag are included. Electricity and bag are included.

Now I have to get 2-3 more sales in this If I go directly, then it will be very difficult Because the salaries are the same It's not like every month, every day It's getting known The trend is also the same The whole year is the same The reason I showed you this part This cost price I showed you this only because You guys said that the money in the bags went up and down Okay, then you guys have this Let's say everything is over after 6 months So in this part, you guys don't need to come When you came here, you said There has been a lot of fluctuation Electricity prices have increased, gas prices have increased Bags prices have increased, transportation has increased Everything has increased Then it will be easier for you guys Instead of calculating everything You will come here and see What did I get now? According to that, you will also see the orders This is completely different from manual work Instead of calculating everything If you put labor and rent in the cost Then I will make an actual entry Let me see We have a particular variant According to its current value We have to calculate the actual cost I want to see if there is any difference between your system and our system Considering if I put direct cost I also put bank cost And

your formula is in the back Our formula is in the memory I want to see if our cost value is the same as yours You tell me what is the value of this I just put it out Very very good
