We have made a first-of-its-own system, which automatically recognizes that a batch of 50 bags has arrived at a particular rate. We have kept 1 lakh bags. Now, it is possible that those 50 bags have been made in 80,000 minutes, and they will be finished in 50 minutes.

Now, the new 50 bags will automatically start delivering to the system at a new rate. What we have to do is that whenever 100-150 bags arrive, as soon as they arrive, we make an entry with a new rate. That will automatically be updated automatically.

We have opened a new production system automatically. Assume that we have started delivering new batches at a rate of 80,000, then it will average out. Will it be like this? It will be like this, but if the amount of bags is too much, like 20 bags are coming from there and 20 bags are coming from here, then it will stop 20 bags first.

It will stop 20 bags first, and 40 bags will go from here at the new price. And when the production is less, as you said, the production is of less meters, then the remaining 50 bags will be consumed. And the price you will go and see, what is the cost per meter, then you will know what will happen to the rate.

I told him that we will do a test entry. Actual test entry. The direct costs involved are grains, electricity, packaging, labor, rent, transportation, miscellaneous.

These are the 7 items that make up the 100% of direct costs. I told him that we will do an entry of one shift and see. It will be guided.

So, let's say you know the rate at 28,600. At 28,600, what was your exact rate? SL's cost. 8.38. It was SL, right? The bag that came at 28,600, the recent bag that came, 50 bags.

It was 8.38. It was 8.38, right? Now you start checking it. What are the costs in this? So that he puts it. And then see, what is the cost of this? How much is the rent? Tell him everything.

Rent is 90,000. Rent is 90,000. Transportation is 1 lakh.

Operator's salary is 1.5 lakh. Labor's salary is 2 lakh 10,000. All this will come in labor's salary.

Petty cash is 60,000. This is your labor and overheads. Then electricity will come directly to the unit.

Scrap will also come directly. Packaging. This will come.

Content price. 400. Tell him the whole packaging.

450. Packaging is 450. Packaging is 450.

But you will have to add one more thing. Variant A comes in 2,500. This is one variant.

I have not added the packaging part yet. You show the total costing. We will go to the judge.

We will show the total costing. How much is the cost? If we start all the direct costs. We will get the SLA level according to grain and electricity.

Everything will be zeroed. Just to see that their formula is not the same as ours. Only grain and electricity.

What will you zero? Packaging will be zeroed. Scrap will be zeroed. Electricity and labor will be zeroed.

Let's see if our SLA critical cost is 2,500 or 6,000. Tell him the formula. What formula did you tell him? He has given the formula.

You told him? What formula did you tell him? How will you put the formula? We told him. We will put it. How did you calculate the cost per meter? What formula did you put? I calculated the electricity.

I calculated the meter and the price of the bag. I calculated the per gram. I calculated it that way.

We have made a proper formula. Based on that. The cost of raw material is 90% and it also varies depending on the grade.

90% cost of raw material, 5.76% of labour and overheads, 1.49% of electricity, 0.75% of scrap and 1.90% of packaging. The cost of raw material, 5.76% of labour and overheads, 1.49% of scrap and 1.90% of packaging. The cost of raw material, 5.76% of labour and overheads, 1.49% of packaging.
